

# A FAST REVIEW OF C (PART 2)

PROGRAMMING LANGUAGES

BY

Z. CIHAN TAYSI

## OUTLINE

- Operators
  - expressions, precedence, associativity
- Control flow
  - if, nested if, switch
  - Looping

## EXPRESSIONS

- Constant expressions
  - 5
  - $5 + 6 * 13 / 3.0$
- Integral expressions (**int j,k**)
  - j
  - $j / k * 3$
  - $k - 'a'$
  - $3 + (\text{int}) 5.0$
- Float expressions (**double x,y**)
  - $x / y * 5$
  - $3 + (\text{float}) 4$
- Pointer expressions (**int \* p**)
  - p
  - $p + 1$
  - "abc"

## PRECEDENCE & ASSOCIATIVITY

- All operators have two important properties called **precedence** and **associativity**.
  - Both properties affect how operands are attached to operators
- Operators with higher precedence have their operands bound, or grouped, to them before operators of lower precedence, regardless of the order in which they appear.
- In cases where operators have the same precedence, associativity (sometimes called binding) is used to determine the order in which operands grouped with operators.

- $2 + 3 * 4$

- $3 * 4 + 2$

- $a + b - c;$

- $a = b = c;$

## PRECEDENCE & ASSOCIATIVITY

Class of operator	Operators in that class	Associativity	Precedence
primary	() [] -> .	Left-to-Right	 <p>HIGHEST</p>
unary	cast operator sizeof & (address of) * (dereference) - + ~ ++ -- !	Right-to-Left	
multiplicative	* / %	Left-to-Right	
additive	+ -	Left-to-Right	
shift	<< >>	Left-to-Right	
relational	< <= > >=	Left-to-Right	
equality	== !=	Left-to-Right	

## PRECEDENCE & ASSOCIATIVITY

Class of operator	Operators in that class	Associativity	Precedence
bitwise AND	&	Left-to-Right	 <p>LOWEST</p>
bitwise exclusive OR	^	Left-to-Right	
bitwise inclusive OR		Left-to-Right	
logical AND	&&	Left-to-Right	
logical OR		Left-to-Right	
conditional	? :	Right-to-Left	
assignment	= += -= *= /= %= >>= <<= &= ^=	Right-to-Left	
comma	,	Left-to-Right	

## PARENTHESIS

- The compiler groups operands and operators that appear within the parentheses first, so you can use parentheses to specify a particular grouping order.
  - $(2 - 3) * 4$
  - $2 - (3 * 4)$

- The inner most parentheses are evaluated first. The expression  $(3+1)$  and  $(8-4)$  are at the same depth, so they can be evaluated in either order.

$$1 + ((3+1) / (8-4) - 5)$$

$$1 + (4 / (8-4) - 5)$$

$$1 + (4 / 4 - 5)$$

$$1 + (1 - 5)$$

$$1 + -4$$

$$-3$$

## BINARY ARITHMETIC OPERATORS

Operator	Symbol	Form	Operation
multiplication	*	$x * y$	x times y
division	/	$x / y$	x divided by y
remainder	%	$x \% y$	remainder of x divided by y
addition	+	$x + y$	x plus y
subtraction	-	$x - y$	x minus y

## THE REMAINDER OPERATOR

- Unlike other arithmetic operators, which accept both integer and floating point operands, the remainder operator accepts only integer operands!
- If either operand is negative, the remainder can be negative or positive, depending on the implementation
- The ANSI standard requires the following relationship to exist between the remainder and division operators
  - $a$  equals  $a \% b + (a/b) * b$  for any integral values of  $a$  and  $b$

## ARITHMETIC ASSIGNMENT OPERATORS

Operator	Symbol	Form	Operation
assign	=	$a = b$	put the value of $b$ into $a$
add-assign	+=	$a += b$	put the value of $a+b$ into $a$
subtract-assign	-=	$a -= b$	put the value of $a-b$ into $a$
multiply-assign	*=	$a *= b$	put the value of $a*b$ into $a$
divide-assign	/=	$a /= b$	put the value of $a/b$ into $a$
remainder-assign	%=	$a \% = b$	put the value of $a \% b$ into $a$

## ARITHMETIC ASSIGNMENT OPERATORS

```
int m = 3, n = 4;
```

```
float x = 2.5, y = 1.0;
```

```
m += n + x - y
```

```
m /= x * n + y
```

```
n %= y + m
```

```
x += y -= m
```

```
m = (m + ((n+x) - y))
```

```
m = (m / ((x*n) + y))
```

```
n = (n % (y + m))
```

```
x = (x + (y = (y - m)))
```

## INCREMENT & DECREMENT OPERATORS

Operator	Symbol	Form	Operation
postfix increment	<b>++</b>	<b>a++</b>	get value of a, then increment a
postfix decrement	<b>--</b>	<b>a--</b>	get value of a, then decrement a
prefix increment	<b>++</b>	<b>++a</b>	increment a, then get value of a
prefix decrement	<b>--</b>	<b>--b</b>	decrement a, then get value of a

## INCREMENT & DECREMENT OPERATORS

```
main () {
    int j=5, k=5;
    printf("j: %d\t k : %d\n", j++, k--);
    printf("j: %d\t k : %d\n", j, k);
    return 0;
}
```

```
main () {
    int j=5, k=5;
    printf("j: %d\t k : %d\n", ++j, --k);
    printf("j: %d\t k : %d\n", j, k);
    return 0;
}
```

## INCREMENT & DECREMENT OPERATORS

```
int j = 0, m = 1, n = -1;
```

```
m++ - --j
```

```
m += ++j * 2
```

```
m++ * m++
```

```
(m++) - (--j) (2)
```

```
m = ( m + ((++j) * 2 ) (3)
```

```
(m++) * (m++) (implementation-dependent)
```

## COMMA OPERATOR

- Comma operator allows you to evaluate two or more distinct expressions wherever a single expression allowed!
  - The result is the value of the rightmost operand
  - for (j = 0, k = 100; k - j > 0; j++, k-- )

## RELATIONAL OPERATORS

Operator	Symbol	Form	Result
greater than	>	<b>a &gt; b</b>	1 if a is greater than b; else 0
less than	<	<b>a &lt; b</b>	1 if a is less than b; else 0
greater than or equal to	>=	<b>a &gt;= b</b>	1 if a is greater than or equal to b; else 0
less than or equal to	<=	<b>a &lt;= b</b>	1 if a is less than or equal to b; else 0
equal to	==	<b>a == b</b>	1 if a is equal to b; else 0
not equal to	!=	<b>a != b</b>	1 if a is NOT equal to b; else 0

## RELATIONAL OPERATORS

```
int j=0, m=1, n=-1;
```

```
float x=2.5, y=0.0;
```

```
j > m
```

```
m/n < x
```

```
j <= m >= n
```

```
++j == m != y * 2
```

```
j > m (0)
```

```
(m / n) < x (1)
```

```
((j <= m) >= n) (1)
```

```
((++j) == m) != (y * 2) (1)
```

## LOGICAL OPERATORS

Operator	Symbol	Form	Result
logical AND	<b>&amp;&amp;</b>	<b>a &amp;&amp; b</b>	1 if a and b are non zero; else 0
logical OR	<b>  </b>	<b>a    b</b>	1 if a or b is non zero; else 0
logical negation	<b>!</b>	<b>!a</b>	1 if a is zero; else 0

## LOGICAL OPERATORS

```
int j=0, m=1, n=-1;
```

```
float x=2.5, y=0.0;
```

```
j && m
```

```
j < m && n < m
```

```
x * 5 && 5 || m / n
```

```
!x || !n || m + n
```

```
(j) && (m) (0)
```

```
(j < m) && (n < m) (1)
```

```
((x * 5) && 5) || (m / n) (1)
```

```
((!x) || !n) || (m + n) (0)
```

## BIT MANIPULATION OPERATORS

Operator	Symbol	Form	Result
right shift	>>	<b>x &gt;&gt; y</b>	x shifted right by y bits
left shift	<<	<b>x &lt;&lt; y</b>	x shifted left by y bits
bitwise AND	&	<b>x &amp; y</b>	x bitwise ANDed with y
bitwise inclusive OR		<b>x   y</b>	x bitwise ORed with y
bitwise exclusive OR (XOR)	^	<b>x ^ y</b>	x bitwise XORed with y
bitwise complement	~	<b>~x</b>	bitwise complement of x

## BIT MANIPULATION OPERATORS

Expression	Binary model of Left Operand	Binary model of the result	Result value
$5 \ll 1$	00000000 00000101	00000000 00001010	10
$255 \gg 3$	00000000 11111111	00000000 00011111	31
$8 \ll 10$	00000000 00001000	00100000 00000000	$2^{13}$
$1 \ll 15$	00000000 00000001	10000000 00000000	$-2^{15}$

Expression	Binary model of Left Operand	Binary model of the result	Result value
$-5 \gg 2$	11111111 11111011	00111111 11111110	$2^{13} - 1$
$-5 \gg 2$	11111111 11111111	11111111 11111110	-2

## BIT MANIPULATION OPERATORS

Expression	Hexadecimal Value	Binary representation
9430	0x24D6	00100100 11010110
5722	0x165A	00010110 01011010
$9430 \& 5722$	0x0452	00000100 01010010

Expression	Hexadecimal Value	Binary representation
9430	0x24D6	00100100 11010110
5722	0x165A	00010110 01011010
$9430   5722$	0x36DE	00110110 11011110

## BIT MANIPULATION OPERATORS

Expression	Hexadecimal Value	Binary representation
9430	0x24D6	00100100 11010110
5722	0x165A	00010110 01011010
9430 ^ 5722	0x328C	00110010 10001100

Expression	Hexadecimal Value	Binary representation
9430	0x24D6	00100100 11010110
~9430	0xDB29	11011011 00101001

## BITWISE ASSIGNMENT OPERATORS

Operator	Symbol	Form	Result
right-shift-assign	>>=	<b>a &gt;&gt;= b</b>	Assign a>>b to a.
left-shift-assign	<<=	<b>a &lt;&lt;= b</b>	Assign a<<b to a.
AND-assign	&=	<b>a &amp;= b</b>	Assign a&b to a.
OR-assign	=	<b>a  = b</b>	Assign a b to a.
XOR-assign	^=	<b>a ^= b</b>	Assign a^b to a.

## CAST & SIZEOF OPERATORS

- Cast operator enables you to convert a value to a different type
- One of the use cases of cast is to promote an integer to a floating point number of ensure that the result of a division operation is not truncated.
  - $3 / 2$
  - `(float) 3 / 2`
- The **sizeof** operator accepts two types of operands: an expression or a data type
  - **the expression may not have type function or void or be a bit field !**
- **sizeof** returns the number of bytes that operand occupies in memory
  - `sizeof (3+5)` returns the size of int
  - `sizeof(short)`

## CONDITIONAL OPERATOR (?:)

Operator	Symbol	Form	Operation
conditional	<b>?:</b>	<b>a ? b : c</b>	if a is nonzero result is b; otherwise result is c

- The conditional operator is the only ternary operator.
- It is really just a shorthand for a common type of *if...else* branch

**`z = ( (x<y) ? x : y );`**

if (x<y)

z = x;

else

z = y;

## MEMORY OPERATORS

Operator	Symbol	Form	Operation
address of	<b>&amp;</b>	<b>&amp;x</b>	Get the address of x.
dereference	<b>*</b>	<b>*a</b>	Get the value of the object stored at address a.
array elements	<b>[]</b>	<b>x[5]</b>	Get the value of array element 5.
dot	<b>.</b>	<b>x.y</b>	Get the value of member y in structure x.
right-arrow	<b>-&gt;</b>	<b>p -&gt; y</b>	Get the value of member y in the structure pointed to by p

## CONTROL FLOW

- Conditional branching
  - if, nested IF
  - switch
- Looping
  - for
  - while
  - do...while

## IF...ELSE STATEMENT

**Ex1 :**

```

if (x)
    statement1;    // executed only if x is nonzero
statement2;        //always executed
  
```

**Ex2:**

```

if (x)
    statement1;    // executed only if x is nonzero
else
    statement2;    // executed only if x is zero
statement3;        //always executed
  
```

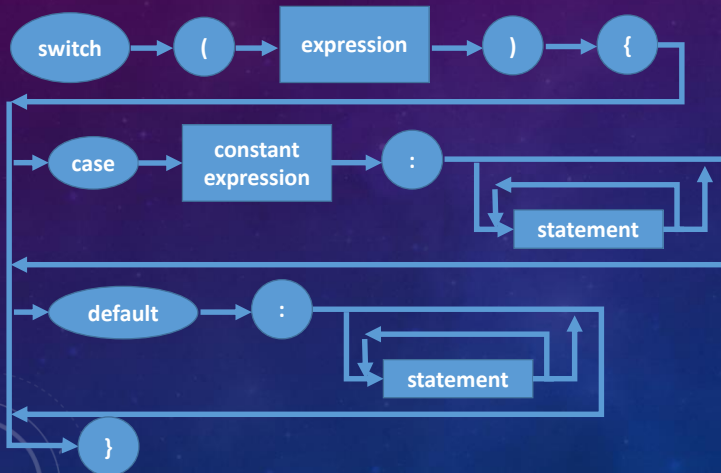

## NESTED IF STATEMENTS

- Note that when an **else** is immediately followed by an **if**, they are usually placed on the same line.
  - this is commonly called an **else if** statement.
- Nested if statements create the problem of matching each else phrase to the right if statement.
  - This is often called the **dangling else** problem !
  - An else is always associated with the nearest previous if.

```

if(a<b)
    if(a<c)
        return a;
    else
        return c;
else if (b<c)
    return b;
else
    return c;
  
```

## SWITCH STATEMENT

- The semantics of the **switch** statement are straight forward. The **switch** expression is evaluated, and if it matches one of the case labels, program flow continues with the statement that follows the matching case label.
  - If none of the case labels match the switch expression, program flow continues at the default label, **if exists!**
- No two case labels may have the same value!
- The default label need not be the last label, though it is good style to put it last

## THE WHILE STATEMENT

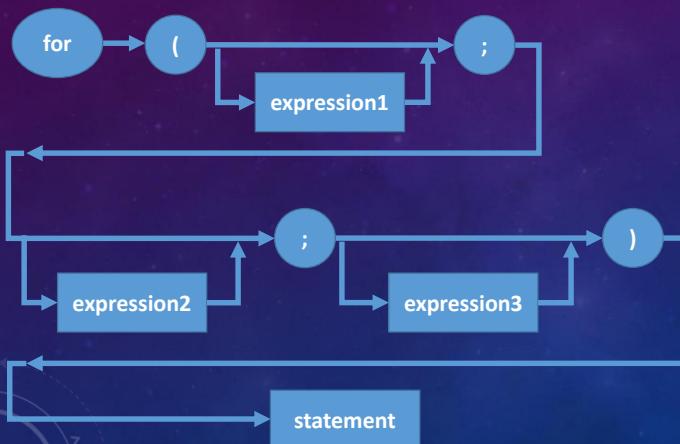

- First the expression is evaluated. If it is a **nonzero** value, statement is executed.
- After statement is executed, program control returns to the top of the while statement, and the process is repeated.
- This continues indefinitely until the expression evaluated to zero.

## THE DO...WHILE STATEMENT

- The only difference between a do..while and a regular while loop is that the test condition is at the bottom of the loop.
  - This means that the program always executes statement *at least one*.

## THE FOR STATEMENT

- First, expression1 is evaluated.
- Then expression2 is evaluated. This is the conditional part of the statement.
- If expression2 is **false**, program control exits the for statement. If expression2 is **true**, the statement is executed.
- After statement is executed, expression3 is evaluated. Then the statement loops back to test expression2 again.

## NULL STATEMENTS

- It is possible to omit one of the expressions in a for loop, it is also possible to omit the body of the for loop.
- **ATTENTION**
- Placing a semicolon after the test condition causes compiler to execute a null statement whenever the if expression is **true**

```
for(c = getchar(); isspace(c); c = getchar());
```

```
if (j == 1);  
    j = 0;
```

## NESTED LOOPS

- It is possible to nest looping statements to any depth
- However, keep that in mind inner loops must finish before the outer loops can resume iterating
- It is also possible to nest control and loop statements together.

```
for( j = 1; j <= 10; j++) {           // outer loop  
    printf("%5d|", j);  
    for( k=1; k <=10; k++) {  
        printf("%5d", j*k);          // inner loop  
    }  
    printf("\n");  
}
```

# BREAK & CONTINUE & GO TO

- ***break***
  - We have already talked about it in [switch statement](#)
  - When used in a loop, it causes program control jump to the statement following the loop
- ***continue***
  - continue statement provides a means for returning to the top of a loop earlier than normal.
  - it is useful, when you want to bypass the reminder of the loop for some reason.
  - Please do NOT use it in any of your C programs.
- ***goto***
  - goto statement is necessary in more rudimentary languages!
  - Please do NOT use it in any of your C programs.
